Instruction of running code

1. main.py: Training and testing the dataset. You can call different CNN models from model folder by just changing model name in main.py. You can also modify data augmentation, training parameter like training epoch, drop out and learning rate in it.
2. helper.py and utils.py are used for data preparation and define evaluation functions for training, validation and test. They are called in main.py.
3. Imagecrop.py split the raw image and label tif files into smaller tiles which are used for train, validation and test dataset.
4. Models folder contains all model files, you need call it from main.py. It also includes pre-trained Resnet models that download from internet.
5. Boundarydatargb folder contains all training, validation, test data and corresponding label image. The class_dict csv file contain the rgb format for each class. Here we have two classes, crop field and boundary.
6. You can select train or test mode in main.py and you only need run main.py file. If you choose train mode, all checkpoints files and validation results for each epoch will be stored in this folder. After your training, when you select test mode, a folder named test will be generated and includes all prediction labels for test dataset.
